

机器学习系列 (3)

提高深度学习性能之 --正则化

深度学习可能会存在过拟合问题，也即有比较高的方差 (variance)，导致深度网络不能很好的泛化，针对这个问题，我们可以有不同的解决方式，比如采用正则化、增加数据集、减小网络规模、改变网络架构等，这个主题我们将讨论正则化。

一、L2范数正则化

- 这种正则化方式是将原交叉信息熵代价函数

$$J = -\frac{1}{m} \sum_{i=1}^m (y^{(i)} \log(a^{[L](i)}) + (1 - y^{(i)}) \log(1 - a^{[L](i)})) \quad (1)$$

更改为

$$J_{regularized} = \underbrace{-\frac{1}{m} \sum_{i=1}^m (y^{(i)} \log(a^{[L](i)}) + (1 - y^{(i)}) \log(1 - a^{[L](i)}))}_{\text{cross-entropy cost}} + \underbrace{\frac{1}{m} \frac{\lambda}{2} \sum_l \sum_k \sum_j W_{kj}^{[l]2}}_{\text{L2 regularization cost}} \quad (2)$$

更改后的代价函数的第二部分中 $W^{[l]2}$ 是范数，称为Frobenius norm,所以在书写时，矩阵 W 写为 $\|W_F\|$ 或 $\|W_2\|$ ，再代价函数增加的第二部分代价称为L2正则化cost。那么在反相传播过程中，

$W = W - learning_rate * dW$,此处的 dW 相较于没有正则化的方式更大了，更新后的 W 将更小，因此我们也称L2范数正则化为权重减轻。

- 那么为什么正则化能够防止过拟合呢？直觉上可以这么认为， W 越小，隐藏层神经元的影响越小，极端情况比如 $W=0$ ，那么对应的神经元就没有发挥作用，神经元的数目越小，越不容易拟合，因此，如果之前是过拟合的情况，经过正则化可以降低方差，当然 W 的大小还与 λ 有关，这就是一个可以调试的参数。

二、L1范数正则化

- L1正则化与L2正则化不同的是，将 $\|W_F\|$ 改为 $\|W_1\|$ ，记为 $\|W_1\|$ ，称L1范数，L1正则化是将平方换成了绝对值。
- L1和L2一样，都是引入对参数 W 的惩罚，“惩罚”意为降低 W 对网络的影响，极端情况就是使 W 中的某些值为0，降低网络的表达能力。
- L1与L2不同的是，L1能够产生稀疏性，L1会趋向于产生少量的特征，而其他的特征都是0，而L2会选择更多的特征，这些特征都会接近于0（详细演绎待补充）

三、L0范数正则化

- L0正则化，L0范数是指向量中非0的元素的个数。如果我们用L0范数来规则化一个参数矩阵 W 的话，就是希望 W 的大部分元素都是0。由此，L0正则化将更大程度上降低网络的表达能力， $\min \|W_0\|$ 在一定条件下，依概率1等价于 $\min \|W_1\|$ ，但L0范数优化是个NP-hard问题，人们于是倾向于用L1,L2范数。

四、dropout正则化

- 这种正则化方式是将隐藏层的神经元随机消除，可以理解为随机抛弃了某些已经学习到的特征，以达到降低网络表达能力的效果。这和PCA有点类似，PCA是对输入层数据进行特征选择，而dropout是对隐藏层学习到的特征进行（随机）选择，不依赖于某一特征，这样可以降低网络对某些参数的过拟合。

五、Early stopping

- 提前停止，这种方式是通过迭代次数和代价两者的曲线，取一个中等大小的迭代次数，此时对应中等大小的 W ，可以防止过拟合。

六、数据扩增

- 如果数据量过少，则深度血虚可能会产生过拟合，那么通过人工产生新的数据，则可以扩大数据集，对于图像识别比如将图片翻转、裁剪等，对于数字识别将数字扭曲，旋转等，通过增加数据量减少过拟合。

Regularization

Welcome to the second assignment of this week. Deep Learning models have so much flexibility and capacity that **overfitting can be a serious problem**, if the training dataset is not big enough. Sure it does well on the training set, but the learned network **doesn't generalize to new examples** that it has never seen!

You will learn to: Use regularization in your deep learning models.

Let's first import the packages you are going to use.

In [1]:

```
# import packages
import numpy as np
import matplotlib.pyplot as plt
from reg_utils import sigmoid, relu, plot_decision_boundary, initialize_parameters, load_2D_dataset,
from reg_utils import compute_cost, predict, forward_propagation, backward_propagation, update_parameters
import sklearn
import sklearn.datasets
import scipy.io
from testCases import *

%matplotlib inline
plt.rcParams['figure.figsize'] = (7.0, 4.0) # set default size of plots
plt.rcParams['image.interpolation'] = 'nearest'
plt.rcParams['image.cmap'] = 'gray'
```

C:\Users\BD\代码作业\第二课第一周编程作业\assignment1\reg_utils.py:85: SyntaxWarning:

g: assertion is always true, perhaps remove parentheses?

```
assert(parameters['W' + str(1)].shape == layer_dims[1], layer_dims[1-1])
```

C:\Users\BD\代码作业\第二课第一周编程作业\assignment1\reg_utils.py:86: SyntaxWarning:

g: assertion is always true, perhaps remove parentheses?

```
assert(parameters['W' + str(1)].shape == layer_dims[1], 1)
```

Problem Statement: You have just been hired as an AI expert by the French Football Corporation. They would like you to recommend positions where France's goal keeper should kick the ball so that the French team's players can then hit it with their head.

Figure 1: Football field

The goal keeper kicks the ball in the air, the players of each team are fighting to hit the ball with their head

They give you the following 2D dataset from France's past 10 games.

In [2]:

```
train_X, train_Y, test_X, test_Y = load_2D_dataset()
```

Each dot corresponds to a position on the football field where a football player has hit the ball with his/her head after the French goal keeper has shot the ball from the left side of the football field.

- If the dot is blue, it means the French player managed to hit the ball with his/her head
- If the dot is red, it means the other team's player hit the ball with their head

Your goal: Use a deep learning model to find the positions on the field where the goalkeeper should kick the ball.

Analysis of the dataset: This dataset is a little noisy, but it looks like a diagonal line separating the upper left half (blue) from the lower right half (red) would work well.

You will first try a non-regularized model. Then you'll learn how to regularize it and decide which model you will choose to solve the French Football Corporation's problem.

1 - Non-regularized model

You will use the following neural network (already implemented for you below). This model can be used:

- in *regularization mode* -- by setting the `lambd` input to a non-zero value. We use "lambd" instead of "lambda" because "lambda" is a reserved keyword in Python.
- in *dropout mode* -- by setting the `keep_prob` to a value less than one

You will first try the model without any regularization. Then, you will implement:

- *L2 regularization* -- functions: `"compute_cost_with_regularization()"` and `"backward_propagation_with_regularization()"`
- *Dropout* -- functions: `"forward_propagation_with_dropout()"` and `"backward_propagation_with_dropout()"`

In each part, you will run this model with the correct inputs so that it calls the functions you've implemented. Take a look at the code below to familiarize yourself with the model.

In [3]:

```
def model(X, Y, learning_rate = 0.3, num_iterations = 30000, print_cost = True, lambd = 0, keep_prob = 1):
    """
    Implements a three-layer neural network: LINEAR->RELU->LINEAR->RELU->LINEAR->SIGMOID.

    Arguments:
    X -- input data, of shape (input size, number of examples)
    Y -- true "label" vector (1 for blue dot / 0 for red dot), of shape (output size, number of examples)
    learning_rate -- learning rate of the optimization
    num_iterations -- number of iterations of the optimization loop
    print_cost -- If True, print the cost every 10000 iterations
    lambd -- regularization hyperparameter, scalar
    keep_prob -- probability of keeping a neuron active during drop-out, scalar.

    Returns:
    parameters -- parameters learned by the model. They can then be used to predict.
    """

    grads = {}
    costs = []  # to keep track of the cost
    m = X.shape[1]  # number of examples
    layers_dims = [X.shape[0], 20, 3, 1]

    # Initialize parameters dictionary.
    parameters = initialize_parameters(layers_dims)

    # Loop (gradient descent)

    for i in range(0, num_iterations):

        # Forward propagation: LINEAR -> RELU -> LINEAR -> RELU -> LINEAR -> SIGMOID.
        if keep_prob == 1:
            a3, cache = forward_propagation(X, parameters)
        elif keep_prob < 1:
            a3, cache = forward_propagation_with_dropout(X, parameters, keep_prob)

        # Cost function
        if lambd == 0:
            cost = compute_cost(a3, Y)
        else:
            cost = compute_cost_with_regularization(a3, Y, parameters, lambd)

        # Backward propagation.
        assert(lambd==0 or keep_prob==1)  # it is possible to use both L2 regularization and dropout
                                          # but this assignment will only explore one at a time

        if lambd == 0 and keep_prob == 1:
            grads = backward_propagation(X, Y, cache)
        elif lambd != 0:
            grads = backward_propagation_with_regularization(X, Y, cache, lambd)
        elif keep_prob < 1:
            grads = backward_propagation_with_dropout(X, Y, cache, keep_prob)

        # Update parameters.
        parameters = update_parameters(parameters, grads, learning_rate)

        # Print the loss every 10000 iterations
        if print_cost and i % 10000 == 0:
            print("Cost after iteration {}: {}".format(i, cost))
        if print_cost and i % 1000 == 0:
            costs.append(cost)
```

```

# plot the cost
plt.plot(costs)
plt.ylabel('cost')
plt.xlabel('iterations (x1,000)')
plt.title("Learning rate =" + str(learning_rate))
plt.show()

return parameters

```

Let's train the model without any regularization, and observe the accuracy on the train/test sets.

In [4]:

```

parameters = model(train_X, train_Y)
print ("On the training set:")
predictions_train = predict(train_X, train_Y, parameters)
print ("On the test set:")
predictions_test = predict(test_X, test_Y, parameters)

```

Cost after iteration 0: 0.6557412523481002

Cost after iteration 10000: 0.16329987525724202

Cost after iteration 20000: 0.1385164242324576

On the training set:

Accuracy: 0.947867298578

On the test set:

Accuracy: 0.915

The train accuracy is 94.8% while the test accuracy is 91.5%. This is the **baseline model** (you will observe the impact of regularization on this model). Run the following code to plot the decision boundary of your model.

In [5]:

```
plt.title("Model without regularization")
axes = plt.gca()
axes.set_xlim([-0.75, 0.40])
axes.set_ylim([-0.75, 0.65])
plot_decision_boundary(lambda x: predict_dec(parameters, x.T), train_X, train_Y)
```

The non-regularized model is obviously overfitting the training set. It is fitting the noisy points! Lets now look at two techniques to reduce overfitting.

2 - L2 Regularization

The standard way to avoid overfitting is called **L2 regularization**. It consists of appropriately modifying your cost function, from:

$$J = -\frac{1}{m} \sum_{i=1}^m (y^{(i)} \log(a^{[L](i)}) + (1 - y^{(i)}) \log(1 - a^{[L](i)})) \quad (1)$$

To:

$$J_{\text{regularized}} = \underbrace{-\frac{1}{m} \sum_{i=1}^m (y^{(i)} \log(a^{[L](i)}) + (1 - y^{(i)}) \log(1 - a^{[L](i)}))}_{\text{cross-entropy cost}} + \underbrace{\frac{1}{m} \frac{\lambda}{2} \sum_l \sum_k \sum_j W_{kj}^{[l]2}}_{\text{L2 regularization cost}} \quad (2)$$

Let's modify your cost and observe the consequences.

Exercise: Implement `compute_cost_with_regularization()` which computes the cost given by formula (2). To calculate $\sum_k \sum_j W_{kj}^{[l]2}$, use :

```
np.sum(np.square(W1))
```

Note that you have to do this for $W^{[1]}$, $W^{[2]}$ and $W^{[3]}$, then sum the three terms and multiply by $\frac{1}{m} \frac{\lambda}{2}$.

In [6]:

```
# GRADED FUNCTION: compute_cost_with_regularization

def compute_cost_with_regularization(A3, Y, parameters, lambd):
    """
    Implement the cost function with L2 regularization. See formula (2) above.

    Arguments:
    A3 -- post-activation, output of forward propagation, of shape (output size, number of examples)
    Y -- "true" labels vector, of shape (output size, number of examples)
    parameters -- python dictionary containing parameters of the model

    Returns:
    cost - value of the regularized loss function (formula (2))
    """
    m = Y.shape[1]
    W1 = parameters["W1"]
    W2 = parameters["W2"]
    W3 = parameters["W3"]

    cross_entropy_cost = compute_cost(A3, Y) # This gives you the cross-entropy part of the cost

    ### START CODE HERE ### (approx. 1 line)
    L2_regularization_cost = lambd/(2*m)*(np.sum(np.square(parameters["W1"]))+np.sum(np.square(parameters["W2"]))+np.sum(np.square(parameters["W3"])))
    ### END CODER HERE ###

    cost = cross_entropy_cost + L2_regularization_cost

    return cost
```

In [7]:

```
A3, Y_assess, parameters = compute_cost_with_regularization_test_case()

print("cost = " + str(compute_cost_with_regularization(A3, Y_assess, parameters, lambd = 0.1)))

cost = 1.78648594516
```

Expected Output:

cost 1.78648594516

Of course, because you changed the cost, you have to change backward propagation as well! All the gradients have to be computed with respect to this new cost.

Exercise: Implement the changes needed in backward propagation to take into account regularization. The changes only concern $dW1$, $dW2$ and $dW3$. For each, you have to add the regularization term's gradient ($\frac{d}{dW}(\frac{1}{2} \frac{\lambda}{m} W^2) = \frac{\lambda}{m} W$).

In [8]:

```
# GRADED FUNCTION: backward_propagation_with_regularization
```

```
def backward_propagation_with_regularization(X, Y, cache, lambd):
```

```
    """
```

```
    Implements the backward propagation of our baseline model to which we added an L2 regularization
```

```
Arguments:
```

```
X -- input dataset, of shape (input size, number of examples)
```

```
Y -- "true" labels vector, of shape (output size, number of examples)
```

```
cache -- cache output from forward_propagation()
```

```
lambd -- regularization hyperparameter, scalar
```

```
Returns:
```

```
gradients -- A dictionary with the gradients with respect to each parameter, activation and pre-
```

```
"""
```

```
m = X.shape[1]
```

```
(Z1, A1, W1, b1, Z2, A2, W2, b2, Z3, A3, W3, b3) = cache
```

```
dZ3 = A3 - Y
```

```
#### START CODE HERE #### (approx. 1 line)
```

```
dW3 = 1./m * np.dot(dZ3, A2.T) + lambd/m*W3
```

```
#### END CODE HERE ####
```

```
db3 = 1./m * np.sum(dZ3, axis=1, keepdims = True)
```

```
dA2 = np.dot(W3.T, dZ3)
```

```
dZ2 = np.multiply(dA2, np.int64(A2 > 0))
```

```
#### START CODE HERE #### (approx. 1 line)
```

```
dW2 = 1./m * np.dot(dZ2, A1.T) + lambd/m*W2
```

```
#### END CODE HERE ####
```

```
db2 = 1./m * np.sum(dZ2, axis=1, keepdims = True)
```

```
dA1 = np.dot(W2.T, dZ2)
```

```
dZ1 = np.multiply(dA1, np.int64(A1 > 0))
```

```
#### START CODE HERE #### (approx. 1 line)
```

```
dW1 = 1./m * np.dot(dZ1, X.T) + lambd/m*W1
```

```
#### END CODE HERE ####
```

```
db1 = 1./m * np.sum(dZ1, axis=1, keepdims = True)
```

```
gradients = {"dZ3": dZ3, "dW3": dW3, "db3": db3, "dA2": dA2,  
            "dZ2": dZ2, "dW2": dW2, "db2": db2, "dA1": dA1,  
            "dZ1": dZ1, "dW1": dW1, "db1": db1}
```

```
return gradients
```

In [9]:

```
X_assess, Y_assess, cache = backward_propagation_with_regularization_test_case()

grads = backward_propagation_with_regularization(X_assess, Y_assess, cache, lambd = 0.7)
print ("dW1 = "+ str(grads["dW1"]))
print ("dW2 = "+ str(grads["dW2"]))
print ("dW3 = "+ str(grads["dW3"]))
```

```
dW1 = [[-0.25604646  0.12298827 -0.28297129]
        [-0.17706303  0.34536094 -0.4410571 ]]
dW2 = [[ 0.79276486  0.85133918]
        [-0.0957219  -0.01720463]
        [-0.13100772 -0.03750433]]
dW3 = [[-1.77691347 -0.11832879 -0.09397446]]
```

Expected Output:

```
dW1    [[-0.25604646 0.12298827 -0.28297129] [-0.17706303 0.34536094 -0.4410571 ]]
dW2    [[ 0.79276486 0.85133918] [-0.0957219 -0.01720463] [-0.13100772 -0.03750433]]
dW3                                [[-1.77691347 -0.11832879 -0.09397446]]
```

Let's now run the model with L2 regularization ($\lambda = 0.7$). The `model()` function will call:

- `compute_cost_with_regularization` **instead of** `compute_cost`
- `backward_propagation_with_regularization` **instead of** `backward_propagation`

In [10]:

```
parameters = model(train_X, train_Y, lambda = 0.7)
print ("On the train set:")
predictions_train = predict(train_X, train_Y, parameters)
print ("On the test set:")
predictions_test = predict(test_X, test_Y, parameters)
```

Cost after iteration 0: 0.6974484493131264

Cost after iteration 10000: 0.2684918873282239

Cost after iteration 20000: 0.2680916337127301

On the train set:

Accuracy: 0.938388625592

On the test set:

Accuracy: 0.93

Congrats, the test set accuracy increased to 93%. You have saved the French football team!

You are not overfitting the training data anymore. Let's plot the decision boundary.

In [11]:

```
plt.title("Model with L2-regularization")
axes = plt.gca()
axes.set_xlim([-0.75, 0.40])
axes.set_ylim([-0.75, 0.65])
plot_decision_boundary(lambda x: predict_dec(parameters, x.T), train_X, train_Y)
```

Observations:

- The value of λ is a hyperparameter that you can tune using a dev set.
- L2 regularization makes your decision boundary smoother. If λ is too large, it is also possible to "oversmooth", resulting in a model with high bias.

What is L2-regularization actually doing?:

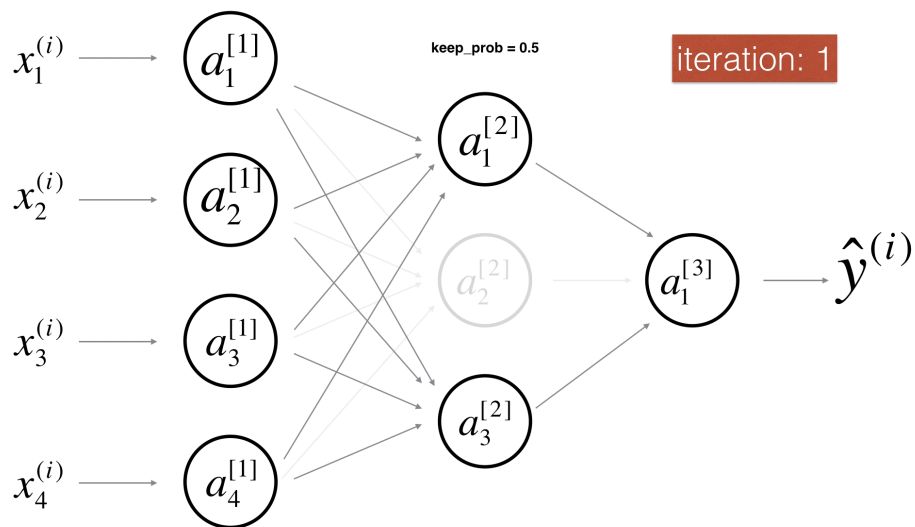

L2-regularization relies on the assumption that a model with small weights is simpler than a model with large weights. Thus, by penalizing the square values of the weights in the cost function you drive all the weights to smaller values. It becomes too costly for the cost to have large weights! This leads to a smoother model in which the output changes more slowly as the input changes.

What you should remember -- the implications of L2-regularization on:

- The cost computation:
 - A regularization term is added to the cost
- The backpropagation function:
 - There are extra terms in the gradients with respect to weight matrices
- Weights end up smaller ("weight decay"):
 - Weights are pushed to smaller values.

3 - Dropout

Finally, **dropout** is a widely used regularization technique that is specific to deep learning. **It randomly shuts down some neurons in each iteration.** Watch these two videos to see what this means!

0:00 / 0:08

Figure 2: Drop-out on the second hidden layer.

At each iteration, you shut down (= set to zero) each neuron of a layer with probability $1 - keep_prob$ or keep it with probability $keep_prob$ (50% here). The dropped neurons don't contribute to the training in both the forward and backward propagations of the iteration.

0:00 / 0:08

Figure 3: Drop-out on the first and third hidden layers.

1st layer: we shut down on average 40% of the neurons. 3rd layer: we shut down on average 20% of the

neurons.

When you shut some neurons down, you actually modify your model. The idea behind drop-out is that at each iteration, you train a different model that uses only a subset of your neurons. With dropout, your neurons thus become less sensitive to the activation of one other specific neuron, because that other neuron might be shut down at any time.

3.1 - Forward propagation with dropout

Exercise: Implement the forward propagation with dropout. You are using a 3 layer neural network, and will add dropout to the first and second hidden layers. We will not apply dropout to the input layer or output layer.

Instructions: You would like to shut down some neurons in the first and second layers. To do that, you are going to carry out 4 Steps:

1. In lecture, we discussed creating a variable $d^{[1]}$ with the same shape as $a^{[1]}$ using `np.random.rand()` to randomly get numbers between 0 and 1. Here, you will use a vectorized implementation, so create a random matrix $D^{[1]} = [d^{1} d^{[1](2)} \dots d^{[1](m)}]$ of the same dimension as $A^{[1]}$.
2. Set each entry of $D^{[1]}$ to be 0 with probability $(1-\text{keep_prob})$ or 1 with probability (keep_prob) , by thresholding values in $D^{[1]}$ appropriately. Hint: to set all the entries of a matrix X to 0 (if entry is less than 0.5) or 1 (if entry is more than 0.5) you would do: $X = (X < 0.5)$. Note that 0 and 1 are respectively equivalent to False and True.
3. Set $A^{[1]}$ to $A^{[1]} * D^{[1]}$. (You are shutting down some neurons). You can think of $D^{[1]}$ as a mask, so that when it is multiplied with another matrix, it shuts down some of the values.
4. Divide $A^{[1]}$ by `keep_prob`. By doing this you are assuring that the result of the cost will still have the same expected value as without drop-out. (This technique is also called inverted dropout.)

In [12]:

```
# GRADED FUNCTION: forward_propagation_with_dropout

def forward_propagation_with_dropout(X, parameters, keep_prob = 0.5):
    """
    Implements the forward propagation: LINEAR -> RELU + DROPOUT -> LINEAR -> RELU + DROPOUT -> LINEAR

    Arguments:
    X -- input dataset, of shape (2, number of examples)
    parameters -- python dictionary containing your parameters "W1", "b1", "W2", "b2", "W3", "b3":
        W1 -- weight matrix of shape (20, 2)
        b1 -- bias vector of shape (20, 1)
        W2 -- weight matrix of shape (3, 20)
        b2 -- bias vector of shape (3, 1)
        W3 -- weight matrix of shape (1, 3)
        b3 -- bias vector of shape (1, 1)
    keep_prob - probability of keeping a neuron active during drop-out, scalar

    Returns:
    A3 -- last activation value, output of the forward propagation, of shape (1,1)
    cache -- tuple, information stored for computing the backward propagation
    """

    np.random.seed(1)

    # retrieve parameters

    A3 = sigmoid(Z3)

    cache = (Z1, D1, A1, W1, b1, Z2, D2, A2, W2, b2, Z3, A3, W3, b3)

    return A3, cache
```

In [13]:

```
X_assess, parameters = forward_propagation_with_dropout_test_case()

A3, cache = forward_propagation_with_dropout(X_assess, parameters, keep_prob = 0.7)
print ("A3 = " + str(A3))

A3 = [[ 0.36974721  0.00305176  0.04565099  0.49683389  0.36974721]]
```

Expected Output:

A3 [[0.36974721 0.00305176 0.04565099 0.49683389 0.36974721]]

3.2 - Backward propagation with dropout

Exercise: Implement the backward propagation with dropout. As before, you are training a 3 layer network. Add dropout to the first and second hidden layers, using the masks $D^{[1]}$ and $D^{[2]}$ stored in the cache.

Instruction: Backpropagation with dropout is actually quite easy. You will have to carry out 2 Steps:

1. You had previously shut down some neurons during forward propagation, by applying a mask $D^{[1]}$ to $A1$. In backpropagation, you will have to shut down the same neurons, by reapplying the same mask $D^{[1]}$ to $dA1$.
2. During forward propagation, you had divided $A1$ by `keep_prob`. In backpropagation, you'll therefore have to divide $dA1$ by `keep_prob` again (the calculus interpretation is that if $A^{[1]}$ is scaled by `keep_prob`, then its derivative $dA^{[1]}$ is also scaled by the same `keep_prob`).

In [14]:

```
# GRADED FUNCTION: backward_propagation_with_dropout

def backward_propagation_with_dropout(X, Y, cache, keep_prob):
    """
    Implements the backward propagation of our baseline model to which we added dropout.

    Arguments:
    X -- input dataset, of shape (2, number of examples)
    Y -- "true" labels vector, of shape (output size, number of examples)
    cache -- cache output from forward_propagation_with_dropout()
    keep_prob - probability of keeping a neuron active during drop-out, scalar

    Returns:
    gradients -- A dictionary with the gradients with respect to each parameter, activation and pre-activation
    """

    m = X.shape[1]
    (Z1, D1, A1, W1, b1, Z2, D2, A2, W2, b2, Z3, A3, W3, b3) = cache

    dZ3 = A3 - Y
    dW3 = 1./m * np.dot(dZ3, A2.T)
    db3 = 1./m * np.sum(dZ3, axis=1, keepdims = True)
    dA2 = np.dot(W3.T, dZ3)
    #### START CODE HERE #### (≈ 2 lines of code)
    dA2 = dA2*D2 # Step 1: Apply mask D2 to shut down the same neurons as during the forward pass
    dA2 = dA2/keep_prob # Step 2: Scale the value of neurons that haven't been shut down
    #### END CODE HERE ####
    dZ2 = np.multiply(dA2, np.int64(A2 > 0))
    dW2 = 1./m * np.dot(dZ2, A1.T)
    db2 = 1./m * np.sum(dZ2, axis=1, keepdims = True)

    dA1 = np.dot(W2.T, dZ2)
    #### START CODE HERE #### (≈ 2 lines of code)
    dA1 = dA1*D1 # Step 1: Apply mask D1 to shut down the same neurons as during the forward pass
    dA1 = dA1/keep_prob # Step 2: Scale the value of neurons that haven't been shut down
    #### END CODE HERE ####
    dZ1 = np.multiply(dA1, np.int64(A1 > 0))
    dW1 = 1./m * np.dot(dZ1, X.T)
    db1 = 1./m * np.sum(dZ1, axis=1, keepdims = True)

    gradients = {"dZ3": dZ3, "dW3": dW3, "db3": db3, "dA2": dA2,

```

Expected Output:

```
dA1                [[ 0.36544439  0. -0.00188233  0. -0.17408748] [ 0.65515713  0. -0.00337459  0. -0. ]]
dA2  [[ 0.58180856  0. -0.00299679  0. -0.27715731] [ 0. 0.53159854 -0. 0.53159854 -0.34089673] [ 0. 0. -0.00292733  0. -0. ]]
```

Let's now run the model with dropout (`keep_prob = 0.86`). It means at every iteration you shut down each neurons of layer 1 and 2 with 24% probability. The function `model()` will now call:

- `forward_propagation_with_dropout` instead of `forward_propagation`.
- `backward_propagation_with_dropout` instead of `backward_propagation`.

In [16]:

```
parameters = model(train_X, train_Y, keep_prob = 0.86, learning_rate = 0.3)

print ("On the train set:")
predictions_train = predict(train_X, train_Y, parameters)
print ("On the test set:")
predictions_test = predict(test_X, test_Y, parameters)
```

Cost after iteration 20000: 0.060582435798513114

On the train set:

Accuracy: 0.928909952607

On the test set:

Accuracy: 0.95

Dropout works great! The test accuracy has increased again (to 95%)! Your model is not overfitting the training set and does a great job on the test set. The French football team will be forever grateful to you!

Run the code below to plot the decision boundary.
